

Prompt migration

Adapt an existing extraction prompt and inspect what changes.

[Open the interactive prototype](#) | Desktop experience. No credentials required.

Problem and user

A developer moving a working extraction workflow from a closed model to Fireworks must inspect failures, revise instructions, and repeat. The hypothesis is that this manual adaptation slows migration even after a candidate model has been selected.

Assumptions

The user has chosen a Fireworks model and can supply a few representative text examples with expected outputs. Their current provider works adequately, and some differences can be addressed with clearer instructions. The intended feature sits inside their existing Fireworks account. These are working assumptions, not validated customer findings.

The workflow

Edit the existing prompt and four invoice examples. Run the test, inspect field-level mismatches, review proposed instruction additions, and rerun against unchanged expected values. Compare improved and newly failing checks, then export the session with both prompts and results. Kimi K2.5 is the illustrative target.

Key choices

Embedded in the console. The feature extends the migration journey within Fireworks, with no separate product or key-entry flow. **One narrow task.** Text invoice extraction and a four-field contract keep the prototype focused. **Explicit checks.** Exact values preserve distinctions such as null, empty strings, and leading zeros. **Reviewable edits.** Additions are visible and expected outputs never change automatically.

What is real and what is simulated

Editing, JSON validation, field comparisons, revision review, and export work in the browser. Responses and suggestions use a deterministic local simulation designed for the sample invoice labels and three clarification rules. No API calls are made; the results do not measure or predict Kimi performance. One ambiguous currency case remains unresolved. Arbitrary document formats and arbitrary prompt behavior are outside the simulation.

Why this and what comes next

Fireworks already offers model recommendations and comparisons. This concept addresses the next task: adapting a prompt and checking a revision. A production version would connect this flow to inference and revision generation through the existing account. I would measure time to a reviewed, passing revision, with regressions on a separate representative dataset as a guardrail.
